

Customer table is a primary key, as there can only be one, customer but it is connected to consession and branched out, because a customer can have more than one consession. The same occurs with tieckets. A customer can buy many tickets, which is why it is branched out.

I used Varchar 50 for customer name, because that will be the length the characters in a customer name. Same goes for email address, and address idm etc, and I adjusted the VARCHAR to what I think the length of the information may be.

Tickets and Movies are connected and branched the same as they both contain an integer for customer_id.
